ON THE IMAGE CONJECTURE

ARNO VAN DEN ESSEN, DAVID WRIGHT, AND WENHUA ZHAO

ABSTRACT. The Image Conjecture was formulated by the third author, who showed that it implied his Vanishing Conjecture, which is equivalent to the famous Jacobian Conjecture. We prove various cases of the Image Conjecture and show that how it leads to another fascinating and elusive assertion that we here dub the Factorial Conjecture. Various cases of the Factorial Conjecture are proved.

1. INTRODUCTION

The notion of a Mathieu subspace was introduced by coauthor Wenhua Zhao in [7], inspired by a conjecture of Olivier Mathieu ([3]), which was shown by Mathieu to imply the famed Jacobian Conjecture. The third author then formulated the Image Conjecture (Conjecture 2.1) upon noticing the resemblance of Mathieu's conjecture with his own Vanishing Conjecture, which he had shown to be equivalent to the Jacobian Conjecture ([6]). He proved that the Image Conjecture, for characteristic zero, implies the Vanishing Conjecture. This connection makes the Image Conjecture a matter of intrigue. The reader is referred to [1] for more details on this story.

We begin by defining a Mathieu subspace. Let k be a field and A a commutative k -algebra. Consider the following two conditions relating to a k -vector subspace \mathcal{M} of A and an element f of A :

$$(M1) \quad f^m \in \mathcal{M} \text{ for all } m \geq 1,$$

and

$$(M2) \quad \text{for any } g \in A, \text{ we have } f^m g \in \mathcal{M} \text{ for } m \gg 0.$$

We will refer to these conditions by their labels (M1) and (M2) throughout this paper.

Definition 1.1. A sub- k -vector space \mathcal{M} of A is called a *Mathieu subspace* if, for all $f \in A$, (M1) implies (M2).

2000 *Mathematics Subject Classification.* Primary: 14R15, 13N10; Secondary: 13A99, 13F20.

Key words and phrases. Mathieu subspace, Jacobian Conjecture, Vanishing Conjecture, Image Conjecture, regular sequence.

The research of the third author was partially supported by NSA Grant H98230-10-1-0168.

It is not difficult to verify that in the definition of Mathieu subspace the condition (M1) can be replaced by

$$(M1') \quad f^m \in \mathcal{M} \text{ for all } m \gg 0,$$

and although (M1) appeared in the original definition of Mathieu subspace given in [7], the authors have of late been stating the definition using (M1'), for the purpose of comparison with the definition of an ideal. A proof of the equivalence of the two definitions has been given in Proposition 2.1 of [9].

We list some basic facts about Mathieu subspaces, which we leave to the reader to verify:

- (1) A and $\{0\}$ are Mathieu subspaces.
- (2) If \mathcal{M} is a Mathieu subspace and $1 \in \mathcal{M}$, then $\mathcal{M} = A$.
- (3) Any ideal in A is a Mathieu subspace.
- (4) The sum $\mathcal{M} + \mathcal{N}$ of two Mathieu subspaces is not necessarily a Mathieu subspace.
(Hint: Use basic facts 2 and 3. Or, see Example 4.12 in [7].)

In the next section we will state the Image Conjecture, for which the notion of a Mathieu subspace is needed, and prove some special cases. Before we proceed, one more definition is in order.

Definition 1.2. For any ring A and variables z_1, \dots, z_n , let $\mathcal{L} : A[z_1, \dots, z_n] \rightarrow A$ be the A -linear map defined by $\mathcal{L}(z^i) = i!$ (meaning $\mathcal{L}(z_1^{\ell_1} \cdots z_n^{\ell_n}) = \ell_1! \cdots \ell_n!$).

Many of the results surrounding the conjecture involve this curious map \mathcal{L} , which will be at the heart of the Factorial Conjecture, introduced and discussed in Section 4.

2. THE IMAGE CONJECTURE

The Image Conjecture, formulated by the third author in [8]¹, goes as follows:

Conjecture 2.1 (Image Conjecture). *Let k be a field and A be a k -algebra, and let $B = A[z_1, \dots, z_n]$ be the polynomial ring in n variables over A . For $a_1, \dots, a_n \in A$ a regular sequence, the image of the A -linear map $B^n \rightarrow B$ defined by $\mathcal{D} = (\partial_{z_1} - a_1, \dots, \partial_{z_n} - a_n)$ is a Mathieu subspace in B .*

We will begin by showing the Image Conjecture is true when k has positive characteristic. We are most interested, though, in the case when k has characteristic zero, from which the Jacobian Conjecture would follow. For the characteristic zero case we have only a partial result for $n = 1$ (Theorem 2.8 below); beyond that the Image Conjecture remains a mystery.

Theorem 2.2. *Let A be an \mathbb{F}_p -algebra, and let $B = A[z_1, \dots, z_n]$ be the polynomial ring in n variables over A . For $a_1, \dots, a_n \in A$ a regular sequence, the image of the A -linear map $B^n \rightarrow B$ defined by $\mathcal{D} = (\partial_{z_1} - a_1, \dots, \partial_{z_n} - a_n)$ is a Mathieu subspace in B .*

¹The formulation in [8] assumes A is a \mathbb{Q} -algebra; however it is more general in its assumption about \mathcal{D} . See Conjecture 1.3 in [8].

Remark 2.3. The theorem fails if we drop the hypothesis that a_1, \dots, a_n forms a regular sequence. This can be seen in the case $n = 1$, $A = \mathbb{F}_p$ (or any field of characteristic p), and $a_1 = 0$. In that case $1 = \partial_z z \in \text{Im } \mathcal{D}$, but $z^{p-1} \notin \text{Im } \mathcal{D}$, so $\text{Im } \mathcal{D}$ is not a Mathieu subspace by item 2 in the Introduction. (This is Example 2.7 in [8]).

Before proving Theorem 2.2 we need some preliminary results, the first of which is a well-known fact about regular sequences.

Lemma 2.4. *Let A be a ring and let a_1, \dots, a_n be a regular sequence A . If $g_1, \dots, g_n \in A$ are such that $\sum_{i=1}^n a_i g_i = 0$, then for each pair (i, j) with $1 \leq i, j \leq n$ and $i \neq j$ there exists an element $g_{ij} \in A$ such that $g_{ij} = -g_{ji}$ for each pair and $g_i = \sum_{j \neq i} g_{ij} a_j$.*

Proof. This follows from the exactness of the Koszul complex for the sequence (a_1, \dots, a_n) (see [4], §18.D). \square

For the rest of this section A, B, a_1, \dots, a_n , and \mathcal{D} will be as in Theorem 2.2, and \mathfrak{a} will denote the ideal $Aa_1 + \dots + Aa_n$ of A . We will write z^r for the monomial $z_1^{r_1} \dots z_n^{r_n}$. For the very next result A does not need to be an \mathbb{F}_p -algebra.

Lemma 2.5. *Let $g \in B = A[z]$ be of degree d , with g_d its degree d homogeneous summand. If $g \in \text{Im } \mathcal{D}$, then all coefficients of g_d belong to the ideal \mathfrak{a} .*

Proof. Being in the image of \mathcal{D} , g has the form

$$(1) \quad g = \sum_{i=1}^n (\partial_{z_i} - a_i) h_i$$

for some $h_1, \dots, h_n \in B$. For $1 \leq i \leq n$ and any integer $m \geq 0$ we will denote by $h_{i,m}$ the degree m homogeneous summand of h_i . Let e be the maximum of the degrees of h_1, \dots, h_n . Since $\deg g = d$, it is clear from (1) that not all of h_1, \dots, h_n can have degree strictly less than d , so we have $e \geq d$. If $e = d$ it follows from (1) that $g_d = -\sum_{i=1}^n a_i h_{i,d}$, and hence that all its coefficients belong to \mathfrak{a} , and we are done.

If $e > d$ then it follows from (1) that $\sum_{i=1}^n a_i h_{i,e} = 0$. We appeal to Lemma 2.4, replacing A with B (which is innocent, since a_1, \dots, a_n is a regular sequence in B as well), which asserts the existence of polynomials $p_{ij,e} \in B$, for $i \neq j$, such that $p_{ij,e} = -p_{ji,e}$ and $h_{i,e} = \sum_{j \neq i} p_{ij,e} a_j$. Since each $h_{i,e}$ is homogeneous of degree e , we can replace $p_{ij,e}$ by its degree e homogeneous summand and assume $p_{ij,e}$ homogeneous of degree e as well.

More generally, we claim that for $m \geq d + 1$ we have, for each pair i, j with $i \neq j$, a polynomial $p_{ij,m}$, homogeneous of degree m and 0 if $m > e$, such that $p_{ij,m} = -p_{ji,m}$ and

$$(2) \quad h_{i,m} = \sum_{j \neq i} (p_{ij,m} a_j - \partial_{z_j} p_{ij,m+1}).$$

Note that the preceding paragraph established exactly this for $m = e$, with $p_{ij,e+1} = 0$ as required. Suppose inductively that the polynomials have been found for larger values of m . Reading equation (1) in degree m gives

$$(3) \quad 0 = \sum_{i=1}^n (\partial_{z_i} h_{i,m+1} - a_i h_{i,m})$$

$$\begin{aligned}
&= \sum_{i=1}^n \left(\partial_{z_i} \left(\sum_{j \neq i} (p_{ij,m+1} a_j - \partial_{z_j} p_{ij,m+2}) \right) - a_i h_{i,m} \right) \\
&= \sum_{i=1}^n \left(\partial_{z_i} \left(\sum_{j \neq i} p_{ij,m+1} a_j \right) - a_i h_{i,m} \right) - \sum_{i \neq j} \partial_{z_i} \partial_{z_j} p_{ij,m+2} \\
&= \sum_{i=1}^n \left(\partial_{z_i} \left(\sum_{j \neq i} p_{ij,m+1} a_j \right) - a_i h_{i,m} \right) \quad (\text{since } \partial_{z_i} \partial_{z_j} p_{ij,m+2} = -\partial_{z_j} \partial_{z_i} p_{ji,m+2}) \\
(4) \quad &= - \sum_{i=1}^n a_i \left(h_{i,m} + \sum_{j \neq i} \partial_{z_j} p_{ij,m+1} \right) \quad (\text{this uses } p_{ij,m+1} = -p_{ji,m+1}).
\end{aligned}$$

From this equation, Lemma 2.4 provides polynomials $p_{ij,m} \in B$ with $p_{ij,m} = -p_{ji,m}$ such that $h_{i,m} + \sum_{j \neq i} \partial_{z_j} p_{ij,m+1} = \sum_{j \neq i} p_{ij,m} a_j$, which, solving for $h_{i,m}$, yields (2).

Finally, we complete the proof by reading (1) in degree d , which gives g_d as the right side of (3) with $m = d$, and hence (following the same reasoning) g_d is equal to (4), with $m = d$. This shows the coefficients of g_d lie in \mathfrak{a} . \square

We now will need to assume that A is an \mathbb{F}_p -algebra.

Corollary 2.6. *Let $f = \sum c_r z^r \in B$ with $c_r \in A$. If $f^p \in \text{Im } \mathcal{D}$, then $c_r^p \in \mathfrak{a}$ for all r .*

Proof. The proof will be by induction on the number d of non-zero homogeneous summands of f . Write $f = f_1 + \dots + f_d$ where f_i are non-zero homogeneous summands with $\deg f_i < \deg f_j$ when $i < j$. Then $f^p = f_1^p + \dots + f_d^p$, and since $f^p \in \text{Im } \mathcal{D}$ Lemma 2.5 says that all coefficients of f_d^p belong to \mathfrak{a} , and this proves the case $d = 1$. In any case f_d^p is the sum of monomials of the form $ca_i z^{pr}$ with $c \in A$, $r = (r_1, \dots, r_n)$, $r_1 + \dots + r_d = \deg f_d$. Since $ca_i z^{pr} = (\partial_i - a_i)(-cz^{rp}) \in \text{Im } \mathcal{D}$, it follows that $f_d^p \in \text{Im } \mathcal{D}$, so $f^p - f_d^p = f_1^p + \dots + f_{d-1}^p \in \text{Im } \mathcal{D}$, and the proof is complete by induction. \square

Lemma 2.7. *For all $r = (r_1, \dots, r_n)$ we have $a_i^p z^r \in \text{Im } \mathcal{D}$.*

Proof. Since $\partial_i^p = 0$ on B , we have $(-a_i)^p z^r = (\partial_i - a_i)^p z^r \in \text{Im } \mathcal{D}$. \square

With these facts the proof of Theorem 2.2 follows quickly.

Proof of Theorem 2.2. We will show, more strongly, that if $f \in B$ with $f^p \in \text{Im } \mathcal{D}$, then for any $g \in B$ we have $f^m g \in \text{Im } \mathcal{D}$ when $m \geq p^2$. Let $f = \sum c_r z^r$ be such that $f^p \in \text{Im } \mathcal{D}$. By Corollary 2.6 we have $c_r^p \in \mathfrak{a}$, hence $c_r^{p^2} \in Aa_1^p + \dots + Aa_n^p$, for all r . Since $f^{p^2} = \sum c_r^{p^2} z^{p^2 r}$, it follows that for every $g \in B$ all coefficients of $f^m g$ belong to $Aa_1^p + \dots + Aa_n^p$ if $m \geq p^2$. Therefore $f^m g \in \text{Im } \mathcal{D}$ by Lemma 2.7. \square

For characteristic zero, the Image Conjecture is not even completely solved in the case $n = 1$. However, the theorem below solves a weak version of this case. Here z represents only one variable.

Theorem 2.8. *If A is a \mathbb{Q} -algebra and if $a \in A$ is a non-zero-divisor such that Aa is a radical ideal, then the image of $\mathcal{D} = \partial_z - a$ is a Mathieu subspace in $B = A[z]$.*

Remark 2.9. The proof of this theorem will appeal to a result from Section 4, namely Theorem 4.9, which says that if $f \in \mathbb{C}[z]$ (z representing one variable) and $\mathcal{L}(f^m) = 0$ for all $m \geq 0$, then $f = 0$. An easy use of the Lefschetz principle shows that the same holds replacing \mathbb{C} by an arbitrary field of characteristic zero.

In the case where a is a unit in A it can be shown rather easily that $\text{Im } \mathcal{D} = B$, hence is a Mathieu subspace. Just note that $\partial_z - a$ has the inverse map $(\partial_z - a)^{-1} = [-a(1 - a^{-1}\partial_z)]^{-1} = -a^{-1} \sum_{i=0}^{\infty} a^{-i} \partial_z^i$, which makes sense because ∂_z is locally nilpotent.

Therefore we make some preparations in the case a is not a unit, in which case $I = \cap_{i=1}^{\infty} Aa^i \neq A$. For $c \in A - I$ there exists a unique integer $m \geq 0$ such that $c \in Aa^m - Aa^{m+1}$. Setting $m = \infty$ if $c \in I$, we call m the a -order of c and denote it by $v_a(c)$. Since a is a non-unit in B as well, v_a extends to elements of B which do not lie in $\cap_{i=1}^{\infty} Ba^i$. It is clear that an element f of B of the form cz^i , then $v_a(f) = v_a(c)$.

In the following proposition \mathcal{D} is as in Theorem 2.8. Here A can be any commutative ring, not necessarily a \mathbb{Q} -algebra.

Proposition 2.10. *Let $a \in A$ be a non-zero-divisor. Let $f = b_0 + b_1z + \cdots + b_dz^d \in A[z]$.*

i) *If $f \in \text{Im } \mathcal{D}$, then $b_d \equiv 0 \pmod{a}$ and*

$$(5) \quad d!b_d + (d-1)!b_{d-1}a + (d-2)!b_{d-2}a^2 + \cdots + b_0a^d \equiv 0 \pmod{a^{d+1}}.$$

ii) *Conversely, let A be either a \mathbb{Q} -algebra or an \mathbb{F}_p -algebra such that $d < p$. If f satisfies (5), then $f \in \text{Im } \mathcal{D}$.*

Proof. For i) we can assume $b_d \neq 0$. If $d = 0$ the two statements coincide and are easy to prove. Assume $d \geq 1$ and $g \in \text{Im } \mathcal{D}$, so that $f = (\partial_z - a)(c_0 + c_1z + \cdots + c_dz^d)$. (Note that the polynomial on the inside must have the same degree as that of f , since a is not a zero-divisor.) In particular $b_d = -ac_d$, establishing the first assertion of i), and therefore $f - (\partial_z - a)(c_dz^d) = b_0 + \cdots + b_{d-2}z^{d-2} + (b_{d-1} - dc_d)z^{d-1} \in \text{Im } \mathcal{D}$. By induction on d we have $(d-1)!(b_{d-1} - dc_d) + (d-2)!b_{d-2}a + \cdots + b_0a^{d-1} \equiv 0 \pmod{a^d}$. Multiplying by a and using $b_d = -ac_d$ gives (5).

For ii), note that the hypothesis and (5) imply that $b_d = -ac_d$ for some $c_d \in A$. If $d = 0$ all is clear. If $d \geq 1$ we again have $f - (\partial_z - a)(c_dz^d) = b_0 + \cdots + b_{d-2}z^{d-2} + (b_{d-1} - dc_d)z^{d-1}$, so $f \in \text{Im } \mathcal{D}$ if and only if $b_0 + \cdots + b_{d-2}z^{d-2} + (b_{d-1} - dc_d)z^{d-1} \in \text{Im } \mathcal{D}$. By induction it suffices to show $(d-1)!(b_{d-1} - dc_d) + (d-2)!b_{d-2}a + \cdots + b_0a^{d-1} \equiv 0 \pmod{a^d}$, or equivalently (since a is a non-zero-divisor), that $(d-1)!(b_{d-1}a - dac_d) + (d-2)!b_{d-2}a^2 + \cdots + b_0a^d \equiv 0 \pmod{a^{d+1}}$. Since $ac_d = -b_d$, this is precisely the hypothesis. \square

Now we return to our assumption that A is a \mathbb{Q} -algebra.

Lemma 2.11. *An element of B of the form cz^i lies in the image of \mathcal{D} if and only if $v_a(c) \geq i + 1$.*

Proof. This is immediate from Proposition 2.10. \square

Corollary 2.12. *Let $f = c_0 + c_1z + \cdots + c_dz^d \in B$. If $v_a(c_i) \geq i + 1$ for $0 \leq i \leq d$, then for each $g \in B$ we have $gf^m \in \text{Im } \mathcal{D}$ for $m \gg 0$.*

Proof. Let $N = \deg g$ and let $m \geq N + 1$. Note that each term cz^j in f^m satisfies $v_a(c) \geq j + m$. Hence each term cz^j of gf^m satisfies $v_a(c) \geq j + m - N \geq j + 1$. By Lemma 2.11 each term of gf^m , and hence gf^m itself, lies in $\text{Im } \mathcal{D}$. \square

Lemma 2.13. *Let $f = c_0 + c_1z + \cdots + c_dz^d \in B$ be such that $v_a(c_i) \geq i$ for $0 \leq i \leq d$, and, for some $t \leq d$, $v_a(c_t) \geq t + 1$. Let $\tilde{f} = f - c_tz^t$. If $f^m \in \text{Im } \mathcal{D}$ for some $m \geq 1$, then $\tilde{f}^m \in \text{Im } \mathcal{D}$.*

Proof. Writing $\tilde{f}^m = f^m + h$ one easily sees that the terms of h satisfy the hypothesis of Lemma 2.11, and so we have $h \in \text{Im } \mathcal{D}$. Since $f^m \in \text{Im } \mathcal{D}$, it follows that $\tilde{f}^m \in \text{Im } \mathcal{D}$. \square

Proof of Theorem 2.8. Let $f = c_0 + c_1z + \cdots + c_dz^d \in B$ be such that $f^m \in \text{Im } \mathcal{D}$ for all $m \geq 1$. We will show that $v_a(c_i) \geq i + 1$ for $0 \leq i \leq d$, which implies $\text{Im } \mathcal{D}$ is a Mathieu subspace by virtue of Corollary 2.12.

Suppose, to the contrary, that $v_a(c_i) \leq i$ for some i . Let t be the maximum of the numbers $i - v_a(c_i)$, which, by our assumption is non-negative. Let $h = a^t f$. Then for each term cz^i of h we have $v_a(c_i) \geq i$, and equality holds for at least one i . Clearly $h^m \in \text{Im } \mathcal{D}$ for all $m \geq 1$. Using Lemma 2.13 to remove the terms for which equality does not hold, we arrive at a polynomial $f = c_0 + c_1z + \cdots + c_dz^d \in B$ with $f^m \in \text{Im } \mathcal{D}$ for all $m \geq 1$ having the property that $v_a(c_i) = i$ when $c_i \neq 0$. We have $c_i = a^i b_i$ with $b_i \in A$, and when $b_i \neq 0$ we have $b_i \notin Aa$. Letting $p = \sum b_i z^i$ we then have $f = p(az)$.

For any $g(z) \in B$, if g has degree $\leq N$ for some integer $N \geq 0$, it follows from Proposition 2.10 that $g(az) \in \text{Im } \mathcal{D}$ if and only if $a^N \mathcal{L}(g) \equiv 0 \pmod{a^{N+1}}$ (\mathcal{L} as in Definition 1.2). Noting that $f^m = p^m(az)$ and $\deg p^m \leq md$ we thereby conclude $a^{md} \mathcal{L}(p^m) \equiv 0 \pmod{a^{md+1}}$ for all $m \geq 1$. Since a is not a zero-divisor, we get $\mathcal{L}(p^m) \equiv 0 \pmod{a}$ for all $m \geq 1$. Let s be the smallest of all i such that $b_i \neq 0$. Then $b_s \notin Aa$. We are assuming Aa is a radical ideal, hence it is the intersection of the prime ideals containing it. Therefore there is a prime ideal \mathcal{P} in A containing Aa but not containing b_s . Letting \bar{p} be the image of p in $k[z]$ where k is the fraction field of A/\mathcal{P} , we have $\bar{p} \neq 0$ and $\mathcal{L}(\bar{p}^m) = 0$. But this contradicts Theorem 4.9 (see Remark 2.9). \square

3. SPECIFIC VERSION OF THE IMAGE CONJECTURE RELEVANT TO THE VANISHING AND JACOBIAN CONJECTURES

The following specific version of the Image Conjecture, from [8], is of special interest. For this we let $\xi = (\xi_1, \dots, \xi_n)$ and $z = (z_1, \dots, z_n)$ be two sets of commuting indeterminates, and we consider the commuting operators $\mathcal{D}_i = \xi_i - \partial_{z_i}$, $1 \leq i \leq n$, on the polynomial ring $A = \mathbb{C}[\xi, z]$. We consider the map $\mathcal{D} = (\mathcal{D}_1, \dots, \mathcal{D}_n) : A^n \rightarrow A$.

Conjecture 3.1 (Special Image Conjecture). *The image of \mathcal{D} is a Mathieu subspace.*

In [8] it is shown that the above conjecture implies the Jacobian Conjecture.² More specifically, it is shown that it suffices to show that

²One has to prove the conjecture for all $n \geq 1$, which then implies the Jacobian Conjecture for all $n \geq 1$.

Theorem 3.2 ([8], Theorem 3.7). *The following two statements are equivalent:*

- (1) *For any $f \in \mathbb{C}[\xi, z]$ of the form $(\xi_1^2 + \dots + \xi_n^2)P$ with $P \in \mathbb{C}[z]$ and P is homogeneous of degree four, then $f^m \in \text{Im } \mathcal{D}$ for all $m \geq 1$ implies that, for each $g \in \mathbb{C}[z]$, $f^m g \in \text{Im } \mathcal{D}$ for all $m \gg 0$.*
- (2) *The Jacobian Conjecture holds in all dimensions $n \geq 1$.*

We now give a realization of the image of \mathcal{D} that is established in [8]. Let \mathcal{E} be the \mathbb{C} -linear map from $\mathbb{C}[\xi, z]$ to $\mathbb{C}[z]$ defined by sending a monomial $\xi_1^{\alpha_1} \dots \xi_n^{\alpha_n} z_1^{\beta_1} \dots z_n^{\beta_n}$ to $\partial_{z_1}^{\alpha_1} \dots \partial_{z_n}^{\alpha_n} z_1^{\beta_1} \dots z_n^{\beta_n}$. Then:

Theorem 3.3 ([8], Theorem 3.1). $\text{Im } \mathcal{D} = \text{Ker } \mathcal{E}$.

This obviously makes it much easier to determine whether an element lies in $\text{Im } \mathcal{D}$, as \mathcal{E} is easy to apply.

We now set $\mathcal{M} = \text{Im } \mathcal{D} (= \text{Ker } \mathcal{E})$ and make a number of observations, letting $A = \mathbb{C}[\xi, z]$ as above, first noting that, by Theorem 3.3, condition (M1) coincides with

$$\mathcal{E}(f^m) = 0 \text{ for all } m \geq 1$$

in this context.

We define a multi-grading on the polynomial ring $\mathbb{C}[\xi, z]$ by setting the multi-degree of a monomial $\xi_1^{i_1} \dots \xi_n^{i_n} z_1^{j_1} \dots z_n^{j_n}$ to be $(j_1 - i_1, \dots, j_n - i_n)$. We also have the ordinary grading on $\mathbb{C}[\xi, z]$ by which ξ_1, \dots, ξ_n each have degree -1 and z_1, \dots, z_n each have degree 1 . The motivation for these choices is the map \mathcal{E} , which preserves z_1, \dots, z_n but converts ξ_1, \dots, ξ_n to operators which lower degree by one. In the discussion below, “multi-degree” refers to the former; “degree” refers to the latter. With $\mathbb{C}[z]$ viewed as a subring of $A = \mathbb{C}[\xi, z]$, these gradings restrict to give a multi-grading and a grading on $\mathbb{C}[z]$. Note that the map $\mathcal{E} : A \rightarrow \mathbb{C}[z]$ preserves both the multi-degree and the degree of a monomial.

- (1) Condition (M2) is satisfied if it holds whenever g is a monomial in A .
- (2) We can write any $f \in A$ as a sum of terms of the form $z_1^{r_1} \dots z_n^{r_n} Q$ where Q has multi-degree $(0, \dots, 0)$, and $(r_1, \dots, r_n) \in \mathbb{Z}^n$. These terms are just the multi-homogeneous summands of f . Any $Q(\xi, z)$ of multi-degree $(0, \dots, 0)$ can be written in the form $q(U_1, \dots, U_n)$ where $U_i = \xi_i z_i$ for $i = 1, \dots, n$.
- (3) If f is multi-homogeneous of multi-degree (r_1, \dots, r_n) , in other words if f has the form $z_1^{r_1} \dots z_n^{r_n} q(U_1, \dots, U_n)$, then:
 - (a) If $r_1, \dots, r_n \geq 0$ then $\mathcal{E}(f) = cz_1^{r_1} \dots z_n^{r_n}$ for some $c \in \mathbb{C}$ (since \mathcal{E} preserves multi-degree).
 - (b) If $r_i < 0$ for some i then $\mathcal{E}(f) = 0$.

Note that if (b) holds for f then it holds for f^m for any $m \geq 1$, hence (M1) holds for f . Moreover it's easy to see that, for any $g \in A$, (b) holds for all multi-homogeneous terms of $f^m g$, for $m \gg 0$, so (M2) holds for f as well.

- (4) For any $f \in A$, let N_f be the convex polyhedron (Newton polyhedron) in \mathbb{R}^n determined by the finite set of points (r_1, \dots, r_n) which are multi-degrees of the nonzero terms $z_1^{r_1} \dots z_n^{r_n} q(U)$ (as above) appearing in f .

- (5) Note that if $f \in A$ is such that there exists i such that the multi-degree of all multi-homogeneous summands of f have negative i -coordinate, then again we have $\mathcal{E}(f^m) = 0$ for all $m \geq 1$ and $\mathcal{E}(f^m g) = 0$ for all $g \in A, m \gg 0$, hence f satisfies (M1) and (M2). This condition simply says that N_f lies in the half space $\{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_i < 0\}$.
- (6) More generally, if there exists a hyperplane $H \subset \mathbb{R}^n$ through the origin such that the strictly positive n -tant $\{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_1, \dots, x_n > 0\}$ and N_f lie strictly on opposite sides of H , then $\mathcal{E}(f^m) = 0$ for all $m \geq 1$ and $\mathcal{L}(f^m g) = 0$ for all $g \in A, m \gg 0$, hence f satisfies (M1) and (M2). This can be seen as follows: There is a nonzero vector $v = (v_1, \dots, v_n) \in \mathbb{R}^n$ such that $v_1, \dots, v_n \geq 0$ and such that $H = \{x \in \mathbb{R}^n \mid (x \cdot v) = 0\}$ (usual inner product). Then $(v \cdot r) < 0$ for all $r \in N_f$. It follows that for all terms $z_1^{s_1} \dots z_n^{s_n} q(U_1, \dots, U_n)$ of f^m , where $m \geq 1$, we must have $(v \cdot s) < 0$, where $s = (s_1, \dots, s_n)$ (in other words all points on the Newton polyhedron of f^m lies below H). Therefore we must have $s_i < 0$ for some i , from which it follows that $\mathcal{E}(f^m) = 0$. Similarly, if $g \in A$ then for sufficiently large m , all points in the Newton polyhedron of $f^m g$ are below H , so that $\mathcal{E}(f^m g) = 0$.
- (7) If $f \in A$ and N_f has an extremal point (r_1, \dots, r_n) corresponding to the term $z^r q(U) = z_1^{r_1} \dots z_n^{r_n} q(U_1, \dots, U_n)$, then the point (mr_1, \dots, mr_n) lies on the Newton polyhedron of f^m (from the term $z^{mr} q(U)^m = z_1^{mr_1} \dots z_n^{mr_n} q(U_1, \dots, U_n)^m$), and in fact is an extremal point. Thus if f satisfies (M1), so does the multi-homogeneous summand $z^r q(U)$.
- (8) We suspect that it cannot happen that a nonzero multi-homogeneous element $z^r q(U)$ with $r_1, \dots, r_n \geq 0$ satisfies (M1). If this suspicion is true, then by the last item, the Newton polyhedron of an $f \in A$ satisfying (M1) cannot have an extremal point in the closed positive n -tant $\{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_1, \dots, x_n \geq 0\}$.
- (9) To address the problem in the previous item, note that if a multi-homogeneous element $f = z_1^{r_1} \dots z_n^{r_n} q(U_1, \dots, U_n)$ satisfies (M1), i.e., $\mathcal{E}(f^m) = 0$ for all $m \geq 1$, then so does $\xi_1^{r_1} \dots \xi_n^{r_n} f = U_1^{r_1} \dots U_n^{r_n} q(U)$, which has multi-degree $(0, \dots, 0)$. Thus we need to show that if $h \in \mathbb{C}[U_1, \dots, U_n]$ and if $\mathcal{E}(h^m) = 0$ for all $m \geq 1$, then $h = 0$. This will be Conjecture 4.2 below.

Recall that $U_i = \xi_i z_i$. One sees that for a monomial $U^\ell = U_1^{\ell_1} \dots U_n^{\ell_n}$ we have $\mathcal{E}(U^\ell) = \ell! = \ell_1! \dots \ell_n!$. Thus the map \mathcal{E} restricted to $\mathbb{C}[U_1, \dots, U_n]$ is precisely the map \mathcal{L} of Definition 1.2. In the conjectures below $U = (U_1, \dots, U_n)$ can be taken to be any system of variables (forgetting ξ and z for the moment), and $\mathcal{L} : \mathbb{C}[U_1, \dots, U_n] \rightarrow \mathbb{C}$ the \mathbb{C} -linear map sending U^ℓ to $\ell!$.

4. THE FACTORIAL CONJECTURE

It follows from the discussion of the preceding section that the following assertion, which draws interest merely by virtue of its simplicity, is necessary for the Image Conjecture to hold.

Conjecture 4.1. *The kernel of $\mathcal{L} : \mathbb{C}[U_1, \dots, U_n] \rightarrow \mathbb{C}$ is a Mathieu subspace.*

As per items 8 and 9 above, we propose the stronger assertion, which we dub the Factorial Conjecture:

Conjecture 4.2 (Factorial Conjecture). *Let $f \in \mathbb{C}[U_1, \dots, U_n]$ be such that $\mathcal{L}(f^m) = 0$ for all $m \geq 1$. Then $f = 0$.*

As seen above, this conjecture would imply that the Newton polyhedron of any $f \in A = \mathbb{C}[\xi, z]$ satisfying (M1) has no extremal points in the closed positive n -tant.

The Factorial Conjecture looks innocent on first glance; one would think it is either easy to prove or else a counterexample should be findable. However no proof or counterexample has yet been given. The authors believe it to be true and will devote quite a bit of effort below in showing that the condition $\mathcal{L}(f^m) = 0$ for all $m \geq 1$ implies $f = 0$ in various situations. In this case we say “the Factorial Conjecture holds for f ”.

As a first observation, let us note that the Factorial Conjecture holds for $f = cM$ where $c \in \mathbb{C}$ and M is a monomial in $\mathbb{C}[U]$, since the condition $\mathcal{L}(f) = 0$ obviously implies $c = 0$. More strongly we have:

Proposition 4.3. *The Factorial Conjecture holds for $f \in \mathbb{C}[U_1, \dots, U_n]$ of the form $c_1M_1 + c_2M_2$, where M_1, M_2 are monomials and $c_1, c_2 \in \mathbb{C}$. More strongly, $\mathcal{L}(f) = \mathcal{L}(f^2) = 0$ implies $f = 0$ in this case.*

The proof will involve the following observation.

Remark 4.4. The one-variable formula $\int_0^\infty U^k e^{-U} dU = k!$ (easily proved inductively using integration by parts) leads to the multi-variable formula

$$\int_{D_n} U^k e^{-U} dU = k!$$

where $U^k = U_1^{k_1} \dots U_n^{k_n}$ and $k! = k_1! \dots k_n!$, $dU = dU_1 \dots dU_n$, and D_n is the non-negative n -tant $U_1 \geq 0, \dots, U_n \geq 0$ in \mathbb{R}^n . It follows that for $f \in \mathbb{C}[U_1, \dots, U_n]$, $\mathcal{L}(f)$ can be realized as

$$(6) \quad \mathcal{L}(f) = \int_{D_n} f(U) e^{-U} dU$$

(which, incidentally, gives a way to calculate $\mathcal{L}(f)$ using a symbolic algebra program such as Maple). Letting $\langle \cdot, \cdot \rangle$ be the Hermitian inner product defined on $\mathbb{C}[U]$ by

$$(7) \quad \langle f, g \rangle = \int_{D_n} f(U) \overline{g(U)} e^{-U} dU$$

we note that this restricts to a positive definite form on $\mathbb{R}[U]$, and that $\mathcal{L}(f^2) = \langle f, f \rangle$, which must be strictly positive if $f \in \mathbb{R}[U]$ and $f \neq 0$.

Proof of Proposition 4.3. We have $\mathcal{L}(f) = c_1L_1 + c_2L_2 = 0$ with $L_1, L_2 \in \mathbb{Z} - \{0\}$, so $c_2 = -c_1L_1/L_2$ and $f = c_1h$ where $h = M_1 - (L_1/L_2)M_2 \in \mathbb{Q}[U] - \{0\}$. From Remark 4.4 we have $0 = \mathcal{L}(f^2) = \langle f, f \rangle = c_1\bar{c}_1\langle h, h \rangle$, which shows $c_1 = 0$, since $\langle h, h \rangle > 0$. By symmetry we have $c_2 = 0$, so $f = 0$. \square

Now we make two remarks that will be important in several of the proofs that follow.³ The first remark shows that to prove the Factorial Conjecture we may assume f has coefficients which are algebraic numbers.

Remark 4.5 (Algebraic reduction). Given a collection of monomials $M_1, \dots, M_d \in \mathbb{C}[U]$ (where U represents U_1, \dots, U_n), we consider whether there exists $f \neq 0$ of the form $\sum_{i=1}^d c_i M_i$ which satisfy $\mathcal{L}(f^m) = 0$ for all $m \geq 1$. Thinking of c_1, \dots, c_d as indeterminates, we note that $\mathcal{L}(f^m)$ is a homogeneous polynomial of degree m in $\mathbb{Z}[c_1, \dots, c_d]$. By the Nullstellensatz, the existence of a nonzero solution is equivalent to saying the polynomials $\mathcal{L}(f^m)$ generate a homogeneous ideal in $\mathbb{Q}[c_1, \dots, c_d]$ whose radical is strictly contained in the ideal generated by the indeterminates c_1, \dots, c_d , which, in turn, is equivalent to the existence of a nonzero solution over $\overline{\mathbb{Q}}$, the algebraic closure of \mathbb{Q} . Similarly, if f has the form $h + \sum_{i=1}^d c_i M_i$ where h is a nonzero polynomial in $\mathbb{Q}[U]$ not involving the monomials M_1, \dots, M_d , then consider the ideal generated by the (non-homogeneous) polynomials $\mathcal{L}(f^m)$ in $\mathbb{Q}[c_1, \dots, c_d]$. The existence of a solution over \mathbb{C} is equivalent to saying this ideal is not all of $\mathbb{Q}[c_1, \dots, c_d]$, which is equivalent to the existence of a solution over $\overline{\mathbb{Q}}$.

Remark 4.6 (Extension of primes). Given any $c_1, \dots, c_d \in \overline{\mathbb{Q}}$, the ring $\mathbb{Q}[c_1, \dots, c_d]$ has a ring extension \mathcal{O} in $\overline{\mathbb{Q}}$ which is integral over $\mathbb{Z}[1/\ell]$, for some $\ell \in \mathbb{Z}$, and we can take \mathcal{O} to be a Dedekind ring (replacing \mathcal{O} by its integral closure). Hence for all but finitely many primes $p \in \mathbb{Z}$ (specifically, those primes not dividing ℓ), $p\mathbb{Z}$ extends to a prime ideal of \mathcal{O} , or, equivalently, \mathcal{O} has a (not necessarily unique) valuation v_p which has positive value at p . We will say “ v_p is a valuation lying over p ”. For $k \in \mathbb{Z}$ it will then be the case that $v_p(k) > 0$ if and only if p divides k in \mathbb{Z} .

Proposition 4.7. *The Factorial Conjecture holds for $f \in \mathbb{C}[U_1, \dots, U_n]$ having the form $f = Mh$ where M is a monomial and h has nonzero constant term.*

Proof. Suppose such an f has the property $\mathcal{L}(f^m) = 0$ for $m \geq 1$. We can assume the constant term of h is 1, and that $h \neq 1$. Then $f = M + c_1 M_1 + \dots + c_d M_d$ where M_1, \dots, M_d are monomials properly divisible by M . For any prime $p \in \mathbb{Z}$ we have

$$(8) \quad f^p = M^p + \sum_{i=1}^d c_i^p M_i^p + p \sum_j g_j(c_1, \dots, c_d) N_j$$

where, for each j , $g_j(c_1, \dots, c_d) \in \mathbb{Z}[c_1, \dots, c_d]$ and N_j is a monomial divisible by M^p . Write $M = U^\alpha$, $M_1 = U^{\alpha_1}$, \dots , $M_d = U^{\alpha_d}$, and $N_j = U^{\beta_j}$. Applying \mathcal{L} to (8) yields

$$(9) \quad \mathcal{L}(f^p) = (p\alpha)! + \sum_{i=1}^d c_i^p (p\alpha_i)! + p \sum_j g_j(c_1, \dots, c_d) \beta_j! = 0.$$

We make two observations: Since M properly divides M_i , we have $\alpha < \alpha_i$, so $(p\alpha)!$ divides $(p\alpha_i)!$ in \mathbb{Z} and moreover, p divides $(p\alpha_i)!/(p\alpha)!$ in \mathbb{Z} . Secondly, since M^p divides N_j , $(p\alpha)!$

³It should be acknowledged that the technique of making reductions using these ideas is due to Mitya Boyarchenko.

divides $(p\beta_j)!$ in \mathbb{Z} . Dividing (9) by $(p\alpha)!$, we get

$$1 + \sum_{i=1}^d c_i^p \frac{(p\alpha_i)!}{(p\alpha)!} + p \sum_j g_j(c_1, \dots, c_d) \frac{\beta_j!}{(p\alpha)!} = 0,$$

which shows that p divides 1 in $\mathbb{Z}[c_1, \dots, c_d]$. However, only finitely many primes can be units in $\mathbb{Z}[c_1, \dots, c_d]$, so choosing p to avoid this finite set brings us to a contradiction. \square

Proposition 4.7 has these two immediate consequences:

Proposition 4.8. *The Factorial Conjecture holds for $f \in \mathbb{C}[U_1, \dots, U_n]$ having nonzero constant term.*

Proof. Apply Proposition 4.7 with $M = 1$. \square

Theorem 4.9. *The Factorial Conjecture holds for $n = 1$.*

Proof. Any nonzero polynomial in one variable has the form $f = Mh$ of Proposition 4.7. \square

The following says something a little different from Proposition 4.7.

Proposition 4.10. *The Factorial Conjecture holds for $f \in \mathbb{C}[U_1, \dots, U_n]$ of the form $cM_0 + \sum_{i=1}^d c_i M_i$ where $M_0 = U_1^{k_1} \dots U_n^{k_n}$ with $k_1 \geq 1$ and $k_1 \geq k_i$ for $i = 2, \dots, n$, $c, c_1, \dots, c_d \in \mathbb{C}$ with $c \neq 0$, and M_1, \dots, M_d are monomials each divisible by $U_1^{k_1+1}$.*

Proof. Assume such an f has the property $\mathcal{L}(f^m) = 0$ for $m \geq 1$. We may assume $c = 1$ and that $c_1, \dots, c_d \in \overline{\mathbb{Q}}$, by Remark 4.5. Choose a Dedekind overring \mathcal{O} of $\mathbb{Z}[c_1, \dots, c_d]$ as in Remark 4.6. Writing

$$\begin{aligned} f^m &= (M_0 + \sum_{i=1}^d c_i M_i)^m \\ &= \sum_{i_0+i_1+\dots+i_d=m} \binom{m}{i_0, i_1, \dots, i_d} c_1^{i_1} \dots c_d^{i_d} M_0^{i_0} M_1^{i_1} \dots M_d^{i_d} \\ &= M_0^m + \sum_{i=1}^m \sum_{i_1+\dots+i_d=i} \frac{m!}{(m-i)!i_1! \dots i_d!} c_1^{i_1} \dots c_d^{i_d} M_0^{m-i} M_1^{i_1} \dots M_d^{i_d}, \end{aligned}$$

we have

$$(10) \quad 0 = \mathcal{L}(f^m) = \mathcal{L}(M_0^m) + \sum_{i=1}^m \sum_{i_1+\dots+i_d=i} \frac{m!}{(m-i)!i_1! \dots i_d!} c_1^{i_1} \dots c_d^{i_d} \mathcal{L}(M_0^{m-i} M_1^{i_1} \dots M_d^{i_d})$$

Let us note that, by our assumption about M_0 , $mk_1 + 1$ does not divide $\mathcal{L}(M_0^m)$ in \mathbb{Z} if $mk_1 + 1$ is prime. Also, by our assumptions about M_1, \dots, M_d , $mk_1 + 1$ does divide each of the terms $\mathcal{L}(M_0^{m-i} M_1^{i_1} \dots M_d^{i_d})$ appearing in (10). Using Dirichlet's prime number theorem⁴ we can select a prime number p of the form $mk_1 + 1$ for which \mathcal{O} has a valuation

⁴which asserts that for any two positive coprime integers a and b , there are infinitely many primes of the form $a + nb$, where $n \geq 0$. See Theorem 66 and Corollary 4.1 in [2].

v_p over p . Viewing (10) as an equation in \mathcal{O} , we see that v_p takes on positive values at each summand $\mathcal{L}(M_0^{m-i} M_1^{i_1} \cdots M_d^{i_d})$. For the first term, however, we have $\mathcal{L}(M_0^m) = k_1! \cdots k_n!$, which is not divisible by p in \mathbb{Z} by our assumption, and hence $v_p(\mathcal{L}(M_0^m)) = 0$. This gives a contradiction, since the sum is 0. \square

Proposition 4.11. *The Factorial Conjecture holds for $f \in \mathbb{C}[U_1, \dots, U_n]$ a power of a linear homogenous form.*

Proof. We have $f = g^r$ where $g = \sum_{i=1}^n c_i U_i$. We concern ourselves with g for a moment. For $m > 0$ an integer we have $g^m = \sum_{i_1 + \dots + i_n = m} \binom{m}{i_1, \dots, i_n} c_1^{i_1} \cdots c_n^{i_n} U_1^{i_1} \cdots U_n^{i_n}$. Thus $\mathcal{L}(g^m) = \sum_{i_1 + \dots + i_n = m} \frac{m!}{i_1! \cdots i_n!} c_1^{i_1} \cdots c_n^{i_n} i_1! \cdots i_n! = m! \sum_{i_1 + \dots + i_n = m} c_1^{i_1} \cdots c_n^{i_n}$. Let us denote by h_m the polynomial $\sum_{i_1 + \dots + i_n = m} c_1^{i_1} \cdots c_n^{i_n}$, viewing c_1, \dots, c_n as indeterminates for the moment.

The polynomials $h_1, h_2, \dots \in \mathbb{C}[c_1, \dots, c_n]$ are related to the elementary symmetric polynomials s_1, \dots, s_n (where $s_m = \sum_{1 \leq i_1 < \dots < i_m \leq n} c_{i_1} \cdots c_{i_m}$) in the following way: Let T be an indeterminate, and set $S(T) = \prod_{i=1}^n (1 - c_i T) = 1 - s_1 T + s_2 T^2 - \dots + (-1)^n s_n T^n$. In $\mathbb{C}[c_1, \dots, c_n][[T]]$ we have $S(T)^{-1} = \prod_{i=1}^n \frac{1}{(1 - c_i T)} = \prod_{i=1}^n (1 + c_i T + c_i^2 T^2 + \dots) = 1 + h_1 T + h_2 T^2 + \dots$, and we let $P(T)$ be the latter power series. Now we specialize to $c_1, \dots, c_n \in \mathbb{C}$ and view $S(T)$ and $P(T)$ as elements of $\mathbb{C}[T]$, $\mathbb{C}[[T]]$, respectively.

Returning to $f = g^r$, we see that our hypotheses $\mathcal{L}(f^m) = 0$ for $m \geq 1$ says that $h_{mr} = 0$ for $m \geq 1$. By Theorem 4.13, we must have $S(T) = 1$, i.e., s_1, \dots, s_n vanish at (c_1, \dots, c_n) . It is well-known (and easily seen) that the only zero of s_1, \dots, s_n is $(0, \dots, 0)$, so we must have $g = 0$. \square

Remark 4.12. In the case where f itself is a linear form one can easily see from the proof that, more strongly, $\mathcal{L}(f) = \mathcal{L}(f^2) = \dots = \mathcal{L}(f^n) = 0$ implies $f = 0$.

Theorem 4.13 (N. Mohan Kumar). *Let $S(T) \in \mathbb{C}[T]$ with constant term 1, and let $P(T) = 1 + a_1 T + a_2 T^2 + \dots$ be its multiplicative inverse in the power series ring $\mathbb{C}[[T]]$. If there exists an integer $r > 0$ such that $a_{mr} = 0$ for all $m \geq 1$, then $S(T) = 1$.*

Proof. We note that $\mathbb{C}[[T]]$ is a free module over $B = \mathbb{C}[[T^r]]$ with basis $\{1, T, \dots, T^{r-1}\}$, and that $\mathbb{C}[T]$ is free over $A = \mathbb{C}[T^r]$ with the same basis. Accordingly, we write $P(T) = B_0 + B_1 T + \dots + B_{r-1} T^{r-1}$ and $S(T) = A_0 + A_1 T + \dots + A_{r-1} T^{r-1}$ with $B_0, \dots, B_{r-1} \in B$, and $A_0, \dots, A_{r-1} \in A$. Our assumption about $P(T)$ clearly shows $B_0 = 1$, since the constant term is the only power of T^r that has non-zero coefficient. Now we tensor $\mathbb{C}[T]$ and $\mathbb{C}[[T]]$ with the rational function field $K = \mathbb{C}(T^r)$, which is the field of fractions of A . This gives the containment $\mathbb{C}[T] \otimes_A K \subset \mathbb{C}[[T]] \otimes_A K$. The first ring is the field $\mathbb{C}(T)$ (since T is algebraic over $\mathbb{C}(T^r)$), which is free over $K = \mathbb{C}(T^r)$ with basis $\{1, T, \dots, T^{r-1}\}$; the second ring is the field of Laurent power series ring $\mathbb{C}[[T]][T^{-1}]$, which is free with the same basis over $L = \mathbb{C}[[T^r]] \otimes_A K = \mathbb{C}[[T^r]][T^{-r}]$, which is the field of Laurent power series in

T^r . So we have:

$$\begin{aligned} S(T) &= A_0 + A_1T + \cdots + A_{r-1}T^{r-1} & 1 + B_1T + \cdots + B_{r-1}T^{r-1} &= P(T) \\ &\quad \cap & \cap \\ &A \oplus AT \oplus \cdots \oplus AT^{r-1} & \subset B \oplus BT \oplus \cdots \oplus BT^{r-1} \\ &\quad \cap & \cap \\ \mathbb{C}(T) &= K \oplus KT \oplus \cdots \oplus KT^{r-1} & \subset L \oplus LT \oplus \cdots \oplus LT^{r-1} \end{aligned}$$

Since $S(T)$ lies in the field $\mathbb{C}(T) = K \oplus KT \oplus \cdots \oplus KT^{r-1}$, so must its inverse $P(T)$, and this shows that B_1, \dots, B_{r-1} lie in $K = \mathbb{C}(T^r)$. Let $Q \in \mathbb{C}[T^r]$ be a common denominator for B_1, \dots, B_{r-1} as rational functions in T^r . Then

$$Q = QP(T)S(T) = (Q + QB_1T + \cdots + QB_{r-1}T^{r-1})S(T).$$

Since Q, QB_1, \dots, QB_{r-1} all lie in $\mathbb{C}[T^r]$ there is no cancellation amongst summands of $Q + QB_1T + \cdots + QB_{r-1}T^{r-1}$. Hence its degree is at least the degree of Q . This shows the degree of $S(T)$ is zero, i.e., $S(T) = 1$, as desired. \square

We have not succeeded in proving that the Factorial Conjecture holds for more general homogeneous polynomials, except in a few situations given below.

Proposition 4.14. *The Factorial Conjecture holds for $f \in \mathbb{C}[U_1, U_2]$ a quadratic homogeneous form in two variables.*

Proof. Writing $f = c_{20}U_1^2 + c_{11}U_1U_2 + c_{02}U_2^2$ we have

$$f^m = \sum_{i+j+k=m} \frac{m!}{i!j!k!} c_{20}^i c_{11}^j c_{02}^k U_1^{2i+j} U_2^{j+2k}$$

so that

$$\begin{aligned} \mathcal{L}(f^m) &= \sum_{i+j+k=m} \frac{m!}{i!j!k!} c_{20}^i c_{11}^j c_{02}^k (2i+j)!(j+2k)! \\ (11) \quad &= \sum_{0 \leq i+k \leq m} \frac{m!}{i!(m-i-k)!k!} c_{20}^i c_{02}^k c_{11}^{m-i-k} (m+i-k)!(m-i+k)! = 0. \end{aligned}$$

Let M be the sum of the terms in above where $k = i$, i.e.,

$$M = \sum_{0 \leq 2i \leq m} \frac{m!}{(i!)^2(m-2i)!} (m!)^2 (c_{20}c_{02})^i c_{11}^{m-2i}.$$

By the integrality reduction (Remark 4.5) we can assume c_{20}, c_{11}, c_{02} lie in a ring \mathcal{O} which is Dedekind and integral over $\mathbb{Z}[1/\ell]$ for some $\ell \in \mathbb{Z}$, $\ell \neq 0$. Let $p = 2r + 1 \in \mathbb{Z}$ be an odd prime which corresponds to a valuation in \mathcal{O} , and consider the above equations with $m = 2r$. Let us note that p divides all of the summands of (11) except those comprised

by M , i.e., those for which $k \neq i$ (for if, say, $i > k$, then $p \mid (m + i - k)!$). Thus we have $\mathcal{L}(f^m) \equiv M \pmod{p}$. From Lemma 4.15 below we get

$$0 \equiv M \equiv \sum_{i=0}^r \binom{r}{i} c_{11}^{2r-2i} (-4c_{20}c_{02})^i = (c_{11}^2 - 4c_{20}c_{02})^r \pmod{p}$$

Hence p divides $(c_{11}^2 - 4c_{20}c_{02})^r$ in \mathcal{O} . This shows that $d = c_{11}^2 - 4c_{20}c_{02}$ has a positive valuation for infinitely many valuations of \mathcal{O} , which shows that $d = 0$. Since d is the discriminant of f , we conclude that f is the square of a linear form in $\mathbb{C}[U_1, U_2]$, so we are in the situation of Proposition 4.11, and the proof is complete, modulo the lemma below. \square

Lemma 4.15. *For $p = 2r + 1 \in \mathbb{Z}$ an odd prime, we have, setting $m = 2r$,*

$$\frac{(m!)^3}{(i!)^2(m-2i)!} \equiv \binom{r}{i} (-4)^i \pmod{p}$$

for $0 \leq i \leq r$.

Proof. We have $m! \equiv -1 \pmod{p}$ by Wilson's Theorem,⁵ so it remains to prove that

$$(12) \quad i!(2r-2i)! \frac{r!}{(r-i)!} (-4)^i \equiv -1 \pmod{p}.$$

To see this, we begin with the expression on the left:

$$\begin{aligned} i!(2r-2i)! \frac{r!}{(r-i)!} (-4)^i &= i!(2r-2i)! r(r-1) \cdots (r-i+1) 2^i (-2)^i \\ &= i!(2r-2i)! 2r(2r-2) \cdots (2r-2i+2) (-2)^i \\ &= \frac{i!(2r)!}{(2r-1)(2r-3) \cdots (2r-2i+1)} (-2)^i \\ &= \frac{i!(p-1)!}{(p-2)(p-4) \cdots (p-2i)} (-2)^i \\ &\equiv \frac{i!(-1)}{(-2)(-4) \cdots (-2i)} (-2)^i \end{aligned}$$

(going mod p and again appealing to Wilson's Theorem)

$$\equiv \frac{i!(-1)}{(i!)(-2)^i} (-2)^i \equiv -1.$$

\square

Proposition 4.16. *The Factorial Conjecture holds for $f \in \mathbb{C}[U_1, \dots, U_n]$ of the form $c_1 U_1^d + \cdots + c_n U_n^d$ where $d \geq 1$.*

⁵Wilson's Theorem: An integer $n > 1$ is prime if and only if $(n-1)! \equiv -1 \pmod{n}$. See [5] for a very nice survey on this.

Proof. The case $d = 1$ is covered in Proposition 4.11, so we assume $d \geq 2$ and each of c_1, \dots, c_n is non-zero. Here we only need to assume that $\mathcal{L}(f^m) = 0$ for $m \gg 0$. We consider the powers f^{nm} of f :

$$f^{nm} = \sum_{k_1 + \dots + k_n = nm} \frac{(nm)!}{k_1! \dots k_n!} c_1^{k_1} \dots c_n^{k_n} U_1^{k_1 d} \dots U_n^{k_n d},$$

which yields

$$\begin{aligned} \mathcal{L}(f^{nm}) &= \sum_{k_1 + \dots + k_n = nm} \frac{(nm)!}{k_1! \dots k_n!} c_1^{k_1} \dots c_n^{k_n} (k_1 d)! \dots (k_n d)! \\ (13) \quad &= (nm)! \sum_{k_1 + \dots + k_n = nm} \frac{(k_1 d)!}{k_1!} \dots \frac{(k_n d)!}{k_n!} c_1^{k_1} \dots c_n^{k_n} \end{aligned}$$

One term of (13), we'll call it the special term, occurs when $k_1 = \dots = k_n = m$. For all other summands we have $k_i > m$ for some i (since $\sum k_i = nm$), and we now examine one of these other summands. Without loss of generality, suppose $k_1 > m$ and write

$$\begin{aligned} \frac{(k_1 d)!}{k_1!} &= \frac{k_1 d}{k_1} (k_1 d - 1) \dots (k_1 d - d + 1) \frac{(k_1 - 1)d}{k_1 - 1} (k_1 d - d - 1) \dots \\ &\quad \dots (2d + 1) \frac{2d}{2} (2d - 1) \dots (d + 1) \frac{1d}{d} (d - 1) \dots 1. \end{aligned}$$

From this one easily sees that $\frac{(k_1 d)!}{k_1!}$ is an integer divisible by $p = (m + 1)d - 1$, which, by Dirichlet's prime number theorem, is prime for infinitely many values of m . As in previous arguments, we apply the algebraic reduction (Remark 4.5) and let \mathcal{O} be the Dedekind ring chosen as in Remark 4.6. For all but finitely many such p , \mathcal{O} has a valuation v_p lying over p . The above observation shows then shows that v_p is positive at all the terms of (13) except the special term, and since $\mathcal{L}(f^{nm}) = 0$ it must be positive at the special term as well. Since $p = (m + 1)d - 1$ does not divide $\frac{(k_1 d)!}{k_1!} \dots \frac{(k_n d)!}{k_n!}$ when $k_1 = \dots = k_n = m$, we must have $v_p(c_1^m \dots c_n^m) = 0$, and since this holds for infinitely many valuations of \mathcal{O} , we conclude $c_1^m \dots c_n^m = 0$. Therefore $c_i = 0$ for some i , contradicting our assumption. \square
